Abstract. *Wibisono FJ, Sumiarto B, Untari T, Effendi MH, Permatasari DA, Witaningrum AM. 2020. Short Communication: Pattern of antibiotic resistance on extended-spectrum beta-lactamases genes producing Escherichia coli on laying hens in Blitar, Indonesia. Biodiversitas 21: 4631-4635.* The aims of this study were to determine the susceptibility pattern of phenotypic antibiotics on extended-spectrum beta-lactamases (ESBL) genes and genotype profiles of ESBL producing *Escherichia coli* strains isolated from cloacal samples of laying hens in Blitar. A total of 165 cloacal swab samples were successfully isolated 145 *E. coli* strains during the study taken from 5 subdistricts in Blitar. All the strains were examined for antibiotic resistance patterns by disk diffusion method with double-disk synergy test (DDST), followed testing with VITEK[®] 2 methods, molecular identification of ESBL coding genes using PCR. The results of this study showed that the characterization of nucleotide analysis from PCR amplification of ESBL-producing *E. coli* bacteria isolated from laying hens in Blitar showed that eight isolates were the dominant of CTX gene, followed by the TEM encoding gene of two isolates, and the SHV coding gene as much as one isolate. The presence of more than 1 encoding genes in the *E. coli* bacterial isolate was seen in 1 isolate, where the isolate carried the CTX gene and the SHV gene as well. All ESBL producing *E. coli* isolates were resistant to amoxicillin, ampicillin, cefazolin, cefotaxime, and ceftriaxone, and these ESBL isolates were more than 70% resistant to gentamicin, aztreonam, and trimethoprim/sulfamethoxazole. These results indicated that poultry is a potential reservoir for ESBL-producing *E. coli*. The presence of ESBL-producing *E. coli* in poultry requires strengthening antibiotic policy. This is important because the regulation of antibiotic use in poultry is gaining momentum to increase animal productivity and food safety in Blitar, Indonesia.

Keywords: Antimicrobial resistance, ESBL genes, *Escherichia coli*, food safety

INTRODUCTION

The use of antibiotics in animal husbandry provides benefits for animals and farmer, but can pose a risk of antibiotic resistance (Suardana et al. 2014). The use of antibiotics without clear indications has caused many bacteria to become resistant (Kurniawati et al. 2015). In developing countries, including in Indonesia, very little data on the prevalence of antibiotic resistance is found. Development of an effective surveillance system needs to be done, to monitor the emergence of antibiotic resistance (Kurniawati et al. 2015). The use of antibiotics in animals can promote the development of antibiotic resistance, one of which is *Escherichia coli* which produces extended-spectrum beta-lactamases (ESBL) enzyme (Hammerum et al. 2014).

Extended-spectrum beta-lactamases is an enzyme that causes resistance to a wider spectrum, third-generation

cephalosporins, and monobactams but does not affect cephamycin or carbapenem that cause resistance so that antibiotics become ineffective (Paterson and Bonomo 2005). Continuous exposure of large amounts of beta-lactam antibiotics induces the production and mutation of the beta-lactamase enzyme. ESBL is derived from the mutated beta-lactamase enzyme. This mutation causes an increase in the enzymatic activity of beta-lactamase, therefore this enzyme can hydrolyze third-generation cephalosporins and aztreonam (Lim et al. 2013; Kang et al. 2017). ESBL-producing bacteria can also be resistant to antibiotics from aminoglycoside, fluoroquinolone, tetracycline, chloramphenicol, and sulfamethoxazole-trimethoprim (Brower et al. 2017; Sudarwanto et al. 2017).

Extended-spectrum beta-lactamases is present in mutated genes often found, namely the type of cefotaximase (CTX-M), temoneira (TEM), and variable sulfhydryl (SHV). The CTX-M, TEM, and SHV genes in

ESBL-producing *E. coli* are genes that encode and produce enzymes that can hydrolyze beta-lactam rings from beta-lactam antibiotics and third-generation cephalosporins. The diagnosis with molecular detection is a test for the beta-lactam ring from beta-lactam class of antibiotics and cephalosporins (Biutifasari 2018). Genotypic confirmatory to see the existence of ESBL encoding genes in *E. coli* bacteria can be carried out by using PCR (Bradford 2001; Putra 2019). The highest prevalence of ESBL-producing bacteria with CTX-M, TEM, and SHV is the most common type of ESBL in poultry (Saliu et al. 2017). Previous research conducted by Brower (2017) found that ESBL producing *E. coli* in India was about 42% in laying hens.

This study was expected to provide a genetic picture of ESBL producing *E. coli*. Data on the existence of reports based on the encoding genes of ESBL producing *E. coli* is clear evidence for monitoring antibiotic use in commercial chicken farms.

MATERIALS AND METHODS

Isolation and identification of *Escherichia coli*

Isolation and identification of *E. coli* were carried out with reference to Effendi et al. (2019). The total samples used in the study were 165 cloacal swabs from 5 subdistricts in Blitar Regency. Cloacal swab samples were stored in the Amies Swab Viscosa (deltalab, Spain) transported to the laboratory in cold temperatures conditions for the isolation of *E. coli* bacteria (Seni et al. 2016). Isolation of *E. coli* bacteria using selective media MacConkey Agar no. 3 CM0115 (Oxoid, England) and differential media Eosin Methylene Blue Agar CM0069 (Oxoid, England), incubated at 35-37°C for 20-24 hours. Pure *E. coli* colonies were identified by biochemical testing of IMVIC (Indol-Motility, Methyl Red, Voges Proskauer, Citrate) and TSIA (Triple Sugar Iron Agar) (Effendi et al. 2019).

ESBL confirmation and antibiotic susceptibility testing

Double disc synergy test (DDST) method was used to evaluate the presence of inhibitory zones of ESBL activity with clavulanic acid using the Kirby-Bauer disk diffusion method on Mueller-Hinton agar (Merck, Germany). The antibiotic discs of amoxicillin-clavulanic 30µg (Oxoid, England), cefotaxime 30µg (Oxoid, England), ceftazidime 30µg (Becton Dickinson, USA), and aztreonam 30µg (Oxoid, England) were used in this method. Culture was incubated at 35-37°C for 18-24 hours (Putra et al. 2020; CLSI 2017). The inhibition zone that appeared on the cup after incubation was measured based on CLSI guidelines showing an inhibition zone ≤ 27 mm in cefotaxime, inhibition zone ≤ 22 mm in ceftazidime, inhibition zone ≤ 27 mm in aztreonam, and there was a synergy between cefotaxime/ceftazidime with a combination of ≤ 22 mm in ceftazidime, inhibition zone ≤ 27 mm in aztreonam, and there was a synergy between cefotaxime/ceftazidime with amoxicillin-clavulanic in the form of synergy expansion of the inhibition zone between the two disks and there is an increase in the inhibition zone ≥ 5 mm between the

diameter of the cephalosporin disk and the cephalosporin-clavulanate disk assert that the *E. coli* bacteria is positive ESBL (CLSI 2017).

The antibiotic sensitivity test of ESBL-producing *E. coli* bacteria by the DDST method was then confirmed by the VITEK[®]2 method. The bacterial suspension was homogenized and bacterial turbidity of 0.50 to 0.63 McFarland was made using VITEK[®]2 DensiCHEK. Antimicrobial susceptibility and phenotypic detection of ESBL generators were used AST N280 cards (bioMérieux, Marcy-L'Étoile, France). Results were analyzed automatically by the system and interpreted as sensitive, intermediate, and resistant (Brower et al. 2017; Biomerieux 2017; Putra et al. 2020).

Characterization of CTX, TEM, and SHV genes by Polymerase Chain Reaction (PCR)

The Extended spectrum beta-lactamase-producing *E. coli* bacteria which has been phenotypically confirmed by DDST and VITEK[®] 2 compact methods were then genotypically confirmed by further analyzing the presence of ESBL genes CTX subtypes, TEM, and SHV using molecular identification of PCR. Bacterial DNA was isolated with the QIAamp[®] DNA mini kit (QIAGEN, Germany). *E. coli* ATCC 35218 was used as a positive control standard for strains of ESBL-producing bacteria and *E. coli* ATCC 25922 was used as a negative control or non-ESBL-producing bacteria. The PCR results were visualized by electrophoresis using 2% agarose gel (Invitrogen, USA). The primers used to encode CTX encoding gene refer to Ali et al. (2016), and the primers used to encode the TEM and SHV coding genes refer to Kurekci et al. (2017), as shown in Table 1.

Ethical clearance

Cloacal swabs were used in this study, hence ethical clearance was not necessary. Cloacal swab samples were collected from laying hens farms in Blitar, East Java province, Indonesia.

RESULTS AND DISCUSSION

Results

The results of isolation and identification of laying cloacal swab samples from a total of 165 samples revealed that 87.9% were identified as presumptive *Escherichia coli* on MacConkey agar media. In order to be identified with *E. coli* colonies, they had a small round shape and semi-mucoid reddish-pink colonies whereas, on Eosin Methylene blue to metallic green colony. The bacterial culture was then confirmed by biochemical tests using IMVIC and TSIA.

The results of the ESBL-producing *E. coli* confirmation on laying hens cloacal swabs with the double-disc synergy test (DDST) method showed 10 (6.89%) positive ESBL isolates. The results were then confirmed by the automatic VITEK[®] 2 compact method which showed 100% *E. coli* results (Table 2). Cefotaxime synergy with the combination of amoxicillin-clavulanate in the form of an expansion of

the inhibition zone between the two disks showed that ESBL is positive. This result is in accordance with Savira (2014). Positive results on ESBL-producing bacteria confirmed that there was an increase in inhibition zones ≥ 5 mm between the diameter of the cephalosporin disk and the cephalosporin-clavulanate disk combination revealed an ESBL positive germ (CLSI 2017).

Molecular identification as shown in Table 3 showed that 8 isolates (8/10, 80%) were isolates of *Escherichia coli* bacteria producing ESBL encoding CTX gene, 2 isolates (2/10, 20%) encoding TEM gene, and 1 isolate (1/10, 10%) encoding the TEM SHV gene. The CTX encoding gene is most commonly found in *E. coli*. CTX type enzymes have hydrophilic ability against cephalosporins, especially cefotaxime, so-called CTX (Saliu et al. 2017). Molecular identification showed visualization of CTX, TEM, and SHV gene fragment bands (Figures 1 and 2). Positive results on the CTX gene showed electrophoresis results of samples describing the same fragments as positive controls with a gene length of 550 bp, as shown on Figure 1. The positive results of the TEM gene on ESBL showed the results of electrophoresis samples illustrating the same fragments as positive controls with a gene length of 1086 bp. The positive results of the SHV gene on ESBL showed the results of electrophoresis samples illustrating the same fragments as positive controls with a gene length of 927 bp (Ali et al. 2016; Kurekci et al. 2017), as shown on Figure 2.

The results of the sensitivity test were in line with the sensitivity test on broiler chickens in the Bogor slaughterhouse of 93.7% (ampicillin), 75% (streptomycin), and 68.75% (erythromycin) (Masruroh et al. 202016). A large number of antibiotics used in laying hens are also used for human therapy, resulting in a selection of pathogenic bacteria that are resistant to several drugs. Sensitivity tests were carried out on all bacterial isolates obtained from bacterial culture.

Figures 1 and 2 showed the spread of ESBL-producing *E. coli* occurring in 3 sub-districts from 5 sub-districts of the sampling area. Srengat subdistrict has 6 isolates, Talun subdistrict has 1 isolate, and Kademangan subdistrict there are 3 isolates of ESBL-producing *E. coli* isolates, while Ponggok subdistrict and Udanawu subdistrict are not found any *E. coli* producing ESBL.

Discussion

The prevalence of *E. coli* producing ESBL in cloacal swabs in laying hens is in accordance with the prevalence of *E. coli* in livestock in slaughterhouses in Bogor by 8.6% (Sudarwanto et al. 2016), but much smaller compared to the incidence of ESBL producing *E. coli* from animal feces of broiler chickens in Bogor by 25% (Masruroh et al. 2016) and the prevalence of ESBL producing *E. coli* in India in laying hens by 42% (Brower et al. 2017).

Extended-spectrum beta-lactamases-producing *E. coli* in poultry spread through the food chain. In Indonesia, the desire to optimize poultry farming has led to the use of antibiotics without referring to pharmaceutical standards, which was similar to research in Zambia (Chishimba et al. 2016). The use of many antibiotics has been reported to be a risk factor for the acquisition of ESBL-producing organisms resulting in a trend of increasing resistance to commonly used antibiotics, namely, ampicillin, cotrimoxazole, gentamicin, erythromycin, tetracycline, and third-generation cephalosporins (Reich et al. 2013).

In Blitar, the antimicrobial agents are used for poultry without proper guidance on drug dispensation. Inadequate monitoring of drug stores in Blitar has made it easy for people to access livestock antibiotics without following the advice recommended by veterinarians thereby increasing the risk of ESBL in poultry products. This is also similar to the condition reported on dairy farms in East Java (Putra et al. 2019). The high prevalence observed may be due to the frequent use of uncontrolled antibiotics for animal health which in turn increases the risk of *E. coli*, being more resistant to antimicrobial strains in normal intestinal flora as observed in a study conducted by Carattoli (2008) and also by Wibisono et al. (2020). Detection of ESBL-producing *E. coli* isolates in poultry has not been fully carried out in Indonesia. Cross-sectional study revealed that overall of almost 10% of ESBL-producing *E. coli* isolates was detected on dogs (Kristaningtyas et al. 2020).

To detect the presence of *E. coli* the cloacal swabs method was used in the present study. Furthermore, high colonization can be associated with cross-contamination of poultry farms potentially causing risk factors that can worsen the transmission rate of ESBL-producing *E. coli*-resistant genes (Lavilla et al. 2008).

The dominant ESBL-producing *E. coli* gene identified in this study was the CTX cluster with 80% which was relatively high in relation to 54.5% of the CTX *E. coli* carriers isolated from poultry in the UK (Randall et al. 2011). In Blitar, the economic situation has caused many residents to grow layer chicken as a business that generates more income. This is what brings humans into close contact with poultry which can be a possible route for releasing environmental ESBL producers. However, there are no detailed studies conducted in Indonesia to specifically explain the types of ESBL-producing *Enterobacteriaceae* associated with chickens and their products. Other studies of poultry products clarify the presence of ESBL gene from *Enterobacteriaceae* (Effendi et al. 2018; Pehlivanoglu et al. 2017). In addition, other researchers also showed that ESBL produced *E. coli* isolates carrying several types of beta-lactamase genes and

that the combination of CTX-was dominant followed by the TEM cluster (Putra et al. 2019).

This study using an antimicrobial susceptibility test with VITEK® 2 compacts in this ESBL isolate revealed an interesting pattern with the level of resistance observed in most of the antimicrobial agents tested. The results on ESBL isolates with 100% antimicrobial susceptibility to amoxicillin, ampicillin, cefazolin, cefotaxime, and ceftriaxone and more than 70% resistant to gentamicin, aztreonam, trimethoprim/sulfamethoxazole were similar the findings of Tutun et al. (2019).

In this study, it was found that isolates ESBL producing *E. coli* have resistance to 2 cephalosporin third-generation class antibiotics. One isolate of ESBL contained two ESBL genes. Therefore, this confirms that the ESBL-mediated plasmid is capable of carrying more than one beta-lactamase gene and thus produces a high level of beta-lactamase resistance phenotype as described by Rottier et al. (2012). These results were in accordance with previous studies on dogs identified that *E. coli* strain consisting of CTX as the main ESBL-producing subtype isolated and also carrying more than one beta-lactamase genes (Kristianingtyas et al. 2020).

In conclusion, molecular identification of CTX, TEM, and SHV genes in ESBL-producing *E. coli* in laying hens cloacal swabs in Blitar Regency was dominant in CTX encoding genes of 8 (8/10, 80%), followed by TEM encoding genes of 2 (2/10, 20%), and while the SHV encoding gene is 1 (1/10, 10%). One isolate ESBL producing *E. coli* was found containing two genes encoding ESBL. These results also indicate the presence of ESBL isolates that are 100% resistant to some antibiotics and also the wider distribution on laying hens in Blitar that can threaten animal health and human health.

ACKNOWLEDGEMENTS

The authors would like to thank the Rector of Airlangga University, Surabaya, Indonesia for providing *Hibah Mandat* research funds with grant numbers; 371/UN3.14/LT/2019, and this article is a part of the research.
